Abstract

It is shown that the quantum error-correction can be achieved by the using of classical binary codes or additive codes over F_4 (see [1],[2],[3]). In this paper with the help of some algebraic techniques the theory of algebraic-geometric codes is used to construct asymptotically good family of quantum error-correcting codes and other classes of good quantum error-correcting codes. Our results are compared with the Tables in [4] and known best quantum codes in [4],[5],[6].

Index terms— quantum error-correcting codes, CSS(Calderbank-Shor-Steane) construction, algebraic-geometric codes

1 Introduction and Preliminaries

Since the pioneering works in [1],[2],[3] now quantum error-correcting codes is rapidly developed and a thorough discussion of the principles of quantum coding theory was offered in [4], and many examples and tables about various bounds were given there. Also many kinds of interesting good quantum codes were constructed by the using of classical binary codes, see,e.g., [5] [6] and [7]. It is natural to consider to use the theory of Algebraic-geometric codes to construct good quantum codes. In this paper, the family of asymptotically good quantum codes is constructed from algebraic-geometric codes over the well-known Garcia-Stichtenoth second tower [8] and some good quantum codes were given by the using of algebraic curves over finite fields of characteristic 2. The general restriction and goodness of the quantum codes from our this construction is also analysed.

The paper is organized as follows. We recall basic results of Calderbank-Shor-Steane construction (CSS codes), one theorem in [7] and the basic construction of algebraic-geometric codes (e.g.,see [10]) below. The family of asymptotically good quantum codes is constructed in section 2. In section 3 we construct some good quantum codes from algebraic curves. The conclusions are presented in the last section.

We recall the following result in [1], [2] or [4].

Theorem 1.1 (Calderbank-Shor-Steane) *Let C_1 and C_2 be two binary codes with parameters $[n, k_1, d_1]$ and $[n, k_2, d_2]$ respectively. Suppose that $C_1^\perp \subset C_2$. Then a quantum $[[n, k_1 + k_2 - n, \min\{d_1, d_2\}]]$ code can be constructed.*

Since we use codes over F_{2^t} sometimes instead of binary codes. We need to recall binary expansion $B(C)$ of a linear F_{2^t} code C with respect to a base B of F_{2^t} over F_2 as in [7]. It is easy to define the expansion $B : F_{2^t} \rightarrow F_2^t$ with respect to the base B . The binary expansion $B(C)$ of the code C is defined componentwise. It is well-known that there exists a self-dual base for the fields of characteristic 2. We need to use the following result of [7].

Theorem 1.2 ([7]) *If B is a self-dual base of F_{2^t} over F_2 . Then the dual*

$B(C)^\perp$ of $B(C)$ is the binary expansion $B(C^\perp)$ of the dual $C^\perp$ of C .

Let X be a genus g smooth, projective, absolutely irreducible curve defined over F_q , P be a set of n F_q -rational points of X and G be a F_q -rational divisor of X , such that, $\text{supp}(G) \cap P = \emptyset$ and $2g - 2 < \deg(G) < n$. Then the functional $C_L(G, P)$ and residue $C_\Omega(G, P)$ algebraic-geometric codes can be defined. It is well-known that the dual of $C_L(G, P)$ is $C_\Omega(G, P)$ (e.g., see [10] Cha.II, section 2). These parameters are as follows.

Theorem 1.3 (e.g., see [10] II.2) *The functional code $C_L(G, P)$ is a $[n, \deg(G) - g + 1, n - \deg(G)]$ linear code over F_q and the residue code $C_\Omega(G, P)$ is a $[n, n - \deg(G) + g - 1, \deg(G) - 2g + 2]$ linear code over F_q .*

2 Asymptotically good quantum codes

Now we recall the results in [8] (see section 3 of [8]) about a tower of function fields $T_1 \subset T_2 \subset T_3 \dots \subset T_i \subset T_{i+1} \dots$ over F_{q^2} attaining the Drinfeld-Vlăduț bound, i.e., $\limsup(N(i)/g(i)) = q - 1$, where $N(i)$ and $g(i)$ are the number of F_{q^2} -rational points and genus of T_i respectively. These function fields are given by $T_1 = F_{q^2}(x_1), \dots, T_{i+1} = T_i(x_{i+1})$, with $x_{i+1}^q + x_{i+1} = x_i^q/(x_i^{q-1} + 1)$. Let X_i be the family of algebraic curves over F_{q^2} corresponding to the function fields T_i . Let Ω be the set of q roots of $y^q + y = 0$ in F_{q^2} . We note that for each value of x_1 in $F_{q^2} \setminus \Omega$, $x_1^q/(x_1^{q-1} + 1) = x_1^{q+1}/(x_1^q + x_1)$ is in the set $F_q \setminus 0$, thus we have q distinct solutions of the equation $\text{Tr}_{F_{q^2}/F_q}(x_2) = x_2^q + x_2 = x_1^q/(x_1^{q-1} + 1)$ in F_{q^2} and each such solution x_2 is in the set $F_{q^2} \setminus \Omega$. Hence we can continue this argument to get at least $(q^2 - q)q^{i-1} = (q - 1)q^i$ F_{q^2} -rational points of the curve X_i (see [8] Lemma 3.9 in p.265). Moreover it is known that the genus $g(2i) = (q^i - 1)^2$ and $g(2i + 1) = (q^{i+1} - 1)(q^{i-1} - 1)$ (see [8], p.265).

From now on we take $q = 2^t$. We take two points $P^{(h)}, Q^{(h)}$ from these $(q - 1)q^h$ F_{q^2} -rational points and let D_h be the set of other $(q - 1)q^h - 2$ F_{q^2} -rational points of X_h . Consider algebraic-geometric functional code $T_1 = C_L(mq^h P^{(h)}, D_h)$ with $2 < m < q - 1$. It is a $[\#D_h, mq^h - g(h) + 1, \#D_h - mq^h]$ linear code over F_{q^2} . Its dual is the algebraic-geometric residue code

$T_1^\perp = C_\Omega(mq^h P^{(h)}, D_h)$. We know the residue code $T_2 = C_\Omega((mq^h P^{(h)} - q^h Q^{(h)}), D_h)$ contains $T_1^\perp$ as a subcode. It is a $[\#D_h, \#D_h - (m-1)q^h + g(h) - 1, (m-1)q^h - 2g(h) + 2]$ code (see Theorem 1.3).

Theorem 2.1 *There exists a family of quantum $[[n_h, k_h, d_h]]$ codes $\{C_h\}$, such that, $R = \lim(k_h/n_h)$ and $\delta = \lim(d_h/n_h)$ are positive and $R + \delta \geq \frac{1}{12}$.*

Proof. We take the binary code $C_1 = B(T_1)$ and $C_2 = B(T_2)$, where B is any given self-dual base of F_{2^t} over F_2 . From Theorem 1.2 $C_1^\perp = B(T_1^\perp)$ is a subcode of C_2 . Thus the condition of Theorem 1.1 is satisfied. We have a quantum $[[n_h, k_h, d_h]]$ code with

$$\begin{aligned} n_h &= 2t((2^t - 1)2^{th} - 2); \\ k_h &= 2t2^{th}; \\ d_h &= \min\{(2^t - 1 - m)2^{th} - 2, (m - 3)2^{th}\} \end{aligned} \quad (2.1)$$

Hence $R = \lim(k_h/n_h) = \frac{1}{2^t - 1}$ and $\delta = \frac{\min\{2^t - 1 - m, m - 3\}}{2^t - 1}$. From the restriction on m we have to take $t \geq 3$, thus, $R = \frac{1}{2^t - 1}$ and $\delta \geq \frac{2^{t-1} - 3}{2^t(2^t - 1)}$, when $m = 2^{t-1}$. We know that R and δ are positive and $R + \delta \geq \frac{1}{4t}$. Thus the conclusion is proved when we take $t = 3$.

From Theorem 2.1 the family of asymptotically good quantum codes is constructed.

3 Quantum codes from curves over F_{2^t}

We consider the quantum codes from Theorem 1.1 by the using of algebraic curves over F_{2^t} .

Theorem 3.1 *Suppose X is an algebraic curve defined over F_{2^t} with N rational points and genus g . Let m, m' be positive integers satisfying $2 < m < N$ and $0 \leq m' < m - 2g + 2$. Then there exist a quantum $[[t(N - 2), tm', \min\{N - 2 - m, m - m' - 2g + 2\}]]$ code.*

Proof. We take 2 rational points P, Q of X and let D be the set of other $N - 2$ rational points. Consider the code $T_1 = C_L(mP, D)$ and $T_2 = C_\Omega((mP - m'Q), D)$. From the well-known fact in algebraic-geometric code theory (see [10]), we have $T_1^\perp = C_\Omega(mP, D)$ is a subcode of T_2 . Let B be any self-dual base of F_{2^t} over F_2 , $C_1 = B(T_1)$ and $C_2 = B(T_2)$. From Theorem 1.2 we have $C_1^\perp = B(T_1^\perp) \subset B(T_2) = C_2$. Thus the condition of Calderbank-Shor-Steane code (Theorem 1.1) is satisfied. It is clear C_1 is a $[t(N - 2), t(m - g + 1), N - 2 - m]$ binary code and C_2 is a $[t(N - 2), t(N - 2 - (m - m') + g - 1), m - m' - 2g + 2]$ binary code from the corresponding parameters of functional and residue algebraic-geometric codes (see Theorem 1.3). Thus from Theorem 1.1 we get our conclusion.

This result offers a lot of quantum codes with flexibility of choices of parameters as in classical algebraic-geometric code theory (see [10] and comparing to quantum codes in [4],[5],[6]). For the existence of algebraic curves with specific (N, g) we refer to G. van der Geer and M. van der Vlugt's list [9]. For example, if we use an algebraic curve over F_4 with $(N, g) = (9, 1)$ (ie. maximal elliptic curve over F_4) we get $[[14, 0, 3]], [[14, 2, 3]], [[14, 4, 2]], [[14, 6, 2]], [[14, 8, 1]]$ quantum codes. When we take curve over F_4 with $(N, g) = (17, 5)$ in [9], we get $[[30, 0, 3]], [[30, 2, 3]], [[30, 4, 2]], [[30, 6, 2]], [[30, 8, 1]]$ quantum codes.

From Theorem 3.1, the projective curves over F_{2^t} with $(N, g) = (2^t + 1, 0)$ can be used to construct quantum codes.

Corollary 3.2 *Let t, m, m' be positive integers with $m < m' < 2^t - 1$. We have a $[[t(2^t - 1), tm', \min\{2^t - 1 - m, m - m' + 2\}]]$ quantum codes.*

Proof. This is direct from Theorem 3.1.

It is well-known that maximal elliptic curve, ie., curves with $(N, g) = (4^t + 2^{t+1} + 1, 1)$, exist for any field $F_{2^{2t}}$ (e.g., see [11]). We have the following result.

Corollary 3.3 *Let t, m, m' be positive integers and suppose $m' < m < 4^t + 2^{t+1} - 1$. Then there exists a $[[2t(4^t + 2^{t+1} - 1), 2tm', \min\{4^t + 2^{t+1} - 1 - m, m - m'\}]]$ quantum codes.*

Proof. This is direct from Theorem 3.1.

Hermitian curves(see [10], VII.4) over $F_{2^{2t}}$ with $(N, g) = (8^t + 1, (2^t - 1)2^{t-1})$ can be used to construct quantum codes as in the following statement.

Corollary 3.4 *Let t, m, m' be positive integers with $2^t(2^t - 1) - 2 < m < 8^t - 1$ and $m' < m - 2^t(2^t - 1) + 2$. We have a $[[2t(8^t - 1), 2tm', \min\{8^t - 1 - m, m - m' - 2^t(2^t - 1) + 2\}]]$ quantum code.*

Proof. This is direct from Theorem 3.1.

4 Conclusions

After computing the short quantum codes constructed from Theorem 3.1 by the using of curves in the list in [9], it seems that these quantum codes cannot reach the highest possible minimum distance in the TableIII of [4]. However as the example given in section 2 we can get a family of asymptotically good quantum codes from algebraic-geometric codes over asymptotically good tower of curves over F_{64} . This phenomenon is similar to the case of classical codes from algebraic-geometric construction. However we think that it is possible to get good lower bound of minimum distance of the binary expansion of algebraic-geometric codes, and thus it seems possible better short quantum codes may be constructed.
